

Final report of Fungal Diversity Study in the Upper Farmington River Watershed

DeWei Li Ph.D.

Mycologist, Department Head/Chief Scientist
The Connecticut Agricultural Experiment Station (CAES) Valley Laboratory

March 7, 2024

The Farmington River holds a crucial position among Connecticut's rivers, serving pivotal roles in ecosystems, the economy, and the well-being of residents. Historically, it played a key role in small-scale manufacturing in towns along its course. Presently, the river predominantly contributes to nature conservation, recreation, and the supply of drinking water. In the past, the Farmington River held significance as one of the chief fishing grounds for the Massaco indigenous people. At present, it continues to be an important heritage site, featuring popular recreational fishing spots along its course. Various activities, including tubing, kayaking, hiking, and swimming, make use of the river and its banks. Beyond its recreational value, the Farmington River plays a vital role in supporting the local ecosystem, providing habitats for vegetation, animals, and fungi. The Upper Farmington River Watershed traverses several state forests, including The American Legion, Peoples SFs (Barkhamsted), Tunxis SF (Harland), Algonquin SF (Colebrook), Nepaug SF (New Hartford), and the reservoirs of The Metropolitan District (MDC).

While plants and animals in the area have been extensively studied, fungi, despite their ubiquitous nature, remain largely unexplored. Fungi, being heterotrophs, differ from plants in their inability to utilize solar energy for carbohydrate synthesis. Instead, they play a crucial role as major biodegraders, breaking down organic compounds and contributing to nutrient cycling in ecosystems. Fungi (including mushrooms) exhibit various nutritional mechanisms, including saprobic, symbiotic, and parasitic, each playing a unique role in maintaining ecological balance. They are essential in decomposing organic matter, forming symbiotic relationships with plants, and even providing medicinal resources. Mushroom fruiting bodies last from several hours, such as some members in the family Coprinaceae to several days. Many mushrooms are ectomycorrhizal fungi, such as *Laccaria*, *Pisolithus*, *Suillus*, *Rhizopogon*, *Gomphidius* and others. Some are saprotrophs. Some are phytopathogens, such as *Armillaria* spp. The fruiting bodies of Polyporales are annual (*Ganoderma tsuga*, *Fistulina americana*) or perennial (*Ganoderma applanatum*, *Fomitopsis pinicola*, *Laetiporus sulphureus*). Many members of the Polyporales are wood decay fungi causing white rots (*Ganoderma tsuga*, *Trametes versicolor*, *Fomes fomentarius* and *Phanerochaete chrysosporium*) or brown rots (*Phaeolus schweinitzii*, and *Fomitopsis pinicola*). Of course some macrofungi are edible, such as *Cantharellus* spp., *Grifola frondosa*, *Morchella* spp., *Laetiporus* spp., *Hydnum repandum*, *Pleurotus ostreatus*, *Fistulina americana* and *Hericium erinaceus* etc.

Since 1991, the estimated number of taxa in the Kingdom Fungi has seen a notable increase, ranging from 1.5 to 2.2-3.8 million species (Hawksworth 2004; Hawksworth and Lücking 2017; Hyde et al. 2020; Hawksworth 1991). Currently, there are accepted species totaling 100,000 to over 130,000 fungi and fungus-like taxa, constituting approximately 2.6–4.5% of the estimated fungal species (Hyde et al. 2020; James et al. 2020). Despite these figures, a considerable number of fungi remain undiscovered, with an annual discovery rate of 1000-2000 new species. Over the past four decades, an average of 1,300 species per year have been described and published (Hawksworth and Lücking 2017).

Over the last 15 years, Connecticut has contributed to this expanding knowledge with the description and publication of a new genus and several species by DeWei Li and coauthors, including *Diaporthe humulicola*, *Metarhiziopsis microspora*, *Phytophthora abietivora* and

Fistulina americana, etc. (Li et al. 2019; Allan-Perkins et al. 2020; Li et al. 2008; Yuan et al. 2022). Recognizing a knowledge gap in fungal diversity within the Farmington River Watershed, understanding this information becomes crucial for effective nature conservation and management.

To address this gap, a study on fungal diversity, specifically macrofungi (including mushrooms and wood decay fungi) was carried out in 2023 in the Upper Farmington River Watershed areas. It is supported by the Farmington River Coordinating Committee. We obtained permission to survey and collect macrofungi (mushrooms and wood decay fungi) in MDC properties, which include Barkhamsted Reservoir, Lake McDonogh, Nepaug Reservoir and West Farmington River section. MDC provided lock numbers so that we could access the gated areas. This survey was done from spring to winter (up to late December) in 2023, collecting specimens with detailed information on sample number, date, location, substrate (wood, soil, leaf litter, moss, needle duff, grass dung, etc.), habitats (forest type), and nearby trees in The American Legion, Peoples State Forests (Barkhamsted), Tunxis State Forest (Harland), Algonquin State Forests (Colebrook), and Nepaug State Forests (New Hartford) and the reservoir areas owned by the Metropolitan District (MDC). Two seasonal assistants and one technician worked on this project full time or part time. One vehicle was rented for the field trips. For the survey, field trips were carried out 2-4 days/week from May to December in the aforementioned areas to collect macrofungal specimens, identify and categorize the fungi in the field as much as we can. The survey covered each area biweekly to monthly so that seasonality of mushroom information became available. The field collections in late fall and early winter (November to December) mainly focused on the members of Polyporales (wood decay fungi), especially the perennial ones, since broadleaf trees have defoliated, and it was easy to find the conks on the trunk. There are several late season mushrooms also. Undetermined ones were brought back to laboratory for further identification with the assistance of literature, various field guides and monographs and lab works. Lab work also involved microscopic morphological studies. Spore prints were made to observe the color of basidiospore deposits. Slides are prepared for morphological study on microscopic features (basidiospore, basidia, basidioles, cystidia, hyphal system, hymenophoral trama, clamp connections) for identification. These fungal characters were observed and measured under two compound microscopes (Olympus BX400) and (Zeiss Imager.M2 with an Axiocam 506 color camera (Carl Zeiss AG Oberkochen, Germany)). Both are equipped with differential interference contrast (DIC). A stereomicroscope (Zeiss Stereo Discover.V20) was also used to observe macrofeatures and certain microfeatures of the mushrooms. Chemical reactions of the mushrooms were tested in the laboratory when it was necessary. Melzer's reagent, ammonia, KOH were used for observing chemical reactions and color changes for identification.

On August 13, 2023, we organized a foray in Peoples State Forest Barkhamsted, Connecticut. Over 40 members of Connecticut Valley Mycological Society and Pioneer Valley Mycological Association participated in this event. The members of the two societies collected 184 fungal species that day.

Two desiccators, four foldable coolers, two orange vests, field tools, paper bags, slides, cover slips, Peri Dishes etc. were purchased for the project. A number of field guides and monographs and a small bookshelf were ordered for identification.

DNA of three *Phaeolus* sp. specimens have been extracted and ITS and LSU loci were sequenced for phylogenetic analyses. The identities of species of *Phaeolus* in the USA need to be clarified. The name *Phaeolus schweinitzii* commonly used in North America may belong to several different species. A recent study showed that *Phaeolus schweinitzii* may only refer to the taxon in Europe and Asia (Yuan et al. 2022). Peck (1980 [1879]) described a species *Polyporus hispidoides* Peck, which was associated with *Picea* and *Pinus* in New York. However, this species was suspected to belong to *Phaeolus*. Thus, it is necessary to conduct further studies on the specimens from CT, NY and other Northeastern states to clarify the species of *Phaeolus*. *Akanthomyces* sp. collected in the area has been cultured and will be sequenced for phylogenetic analyses. Its identity will be determined.

A list of references, books, monographs, and field guides were used to identify the macrofungi (Bessette et al. 1997; Barron 1999; Arora 1986; Baroni 2017; Bessette et al. 2013; Bessette et al. 2000; Beug et al. 2014; Bessette et al. 2017; Bessette et al. 2009; Bessette et al. 2012; Bessette et al. 2021; Breitenbach and Kränzlin 1984; Groves 1962; Bunyard and Justice 2020; Phillips 1991; Martin and Alexopoulos 1969; Stephenson and Stempen 1994; Hesler and Smith 1963; Lincoff 1997; Ryvardeen 1978, 1976; Coker and Couch 1974; 吴兴亮 and 戴玉成 2005; 戴玉成 2009; Kauffman 1971; Smith et al. 1979; Smith et al. 1973). - Phillips R. 1991. Mushrooms of North America. Boston: Little Brown.

In total, 648 species of macrofungi (mushrooms and wood decay fungi, etc.) are collected and categorized in the upper Farmington River areas. Among these species, some species can only be identified to genus level (Table 1). These species are expressed as genus name and sp., such as *Amanita* sp.

With the development of mycology, fungal taxonomy and molecular biology, many fungi experienced name changes in the last 20 years based on phylogenetic analyses. Each name of fungi identified in the study was checked with Index Fungorum (<https://www.indexfungorum.org/names/names.asp>, a mycological database for fungal names and classification) for its current name. The checked scientific names with their authorities are listed in the first column of Table 1.

The whole list of fungi found in the study is presented as Table 1.
